# A beginners guide to solving biological problems in R

Robert Stojnić (rs550), Laurent Gatto (lg390), Rob Foy (raf51), John Davey (jd626) and Dávid Molnár (dm516)

Original slides by Ian Roberts and Robert Stojnić

### Day 1 schedule

- 1. Introduction to R and its environment
- 2. Data structures
- 3. Data analysis example
- 4. Programming techniques

Introduction to R and its environment

1

#### What's R?

- A statistical programming environment
  - based on S
  - Suited to high level data analysis
- Open source & cross platform
- Extensive graphics capabilities
- Diverse range of add-on packages
- Active community of developers
- Thorough documentation

What is R?

#### The R Project for Statistical Computing

#### Getting Started:

- R is a free software environment for statistical computing and graphics. It compiles and runs on a wide variety of UNIX platforms, Windows and MacOS. To download R, please choose your preferred CRAN mirror.
- If you have questions about R like how to download and install the software, or what the license terms are, please read our <u>answers to frequently asked questions</u> before you send an email.

#### News:

- The R Journal Vol.5/1 is available.
- R version 3.0.1 (Good Sport) has been released on 2013-05-16.
- R version 2.15.3 (Security Blanket) has been released on 2013-03-01.
- useR! 2013, will take place at the University of Castilla-La Mancha, Albacete, Spain, July 10-12 2013.

This server is hosted by the Institute for Statistics and Mathematics of WU (Wirtschaftsuniversität Wien).

www.r-project.org

### Various platforms supported

- Release 3.1.0 (April 2014)
  - Base package
  - Contributed packages (general purposes extras)
  - >5400 available packages
- Download from http://www.stats.bris.ac.uk/R/
- Windows, Mac and Linux versions available
- Executed using command line, or a graphical user interface (GUI)
- On this course, we use the RStudio GUI (www.rstudio.com)
- Everything you need is installed on the training machines
- If you are using your own machine, download both R and RStudio

### **Getting Started**

- R is a program which, once installed on your system, can be launched and is immediately ready to take input directly from the user
- There are two ways to launch R:
  - 1) From the command line (particularly useful if you're quite familiar with Linux)
  - 2) As an application called RStudio (very good for beginners)

#### Prepare to launch R

#### From command line

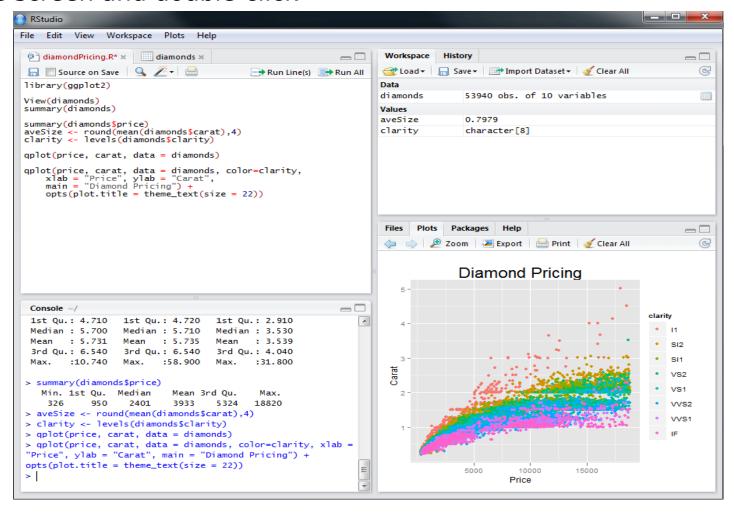

- To start R in Linux we need to enter the Linux console (also called Linux terminal and Linux shell)
- To start R, at the prompt simply type:

\$ R

• If R doesn't print the welcome message, call us to help!

## Prepare to launch R Using RStudio

 To launch RStudio, find the RStudio icon in the menu bar on the left of the screen and double-click

### The Working Directory (wd)

- Like many programs R has a concept of a working directory (wd)
- It is the place where R will look for files to execute and where it will save files, by default
- For this course we need to set the working directory to the location of the course scripts
- At the command prompt in the terminal or in RStudio console type:

```
> setwd("R_course/Day_1_scripts")
```

- Alternatively in RStudio use the mouse and browse to the directory location
- Session → Set Working Directory → Choose Directory...

## Basic concepts in R command line calculation

The command line can be used as a calculator. Type:

```
> 2 + 2
[1] 4

> 20/5 - sqrt(25) + 3^2
[1] 8

> sin(pi/2)
[1] 1
```

 Note: The number in the square brackets is an indicator of the position in the output. In this case the output is a 'vector' of length 1 (i.e. a single number). More on vectors coming up...

## Basic concepts in R variables

A variable is a letter or word which takes (or contains) a value. We
use the assignment 'operator', <-</li>

```
> x <- 10
> x
[1] 10
> myNumber <- 25
> myNumber
[1] 25
```

• We can perform arithmetic on variables:

```
> sqrt(myNumber)
[1] 5
```

We can add variables together:

```
> x + myNumber
[1] 35
```

## Basic concepts in R variables

We can change the value of an existing variable:

```
> x <- 21
> x
[1] 21
```

• We can set one variable to equal the value of another variable:

```
> x <- myNumber
> x
[1] 25
```

• We can modify the contents of a variable:

```
> myNumber <- myNumber + sqrt(16)
[1] 29</pre>
```

### Basic concepts in R functions

- **Functions** in R perform operations on **arguments** (the input(s) to the function). We have already used **sin(x)** which returns the sine of **x**. In this case the function has one argument, **x**. Arguments are *always* contained in parentheses, i.e. curved brackets (), separated by commas.
- Try these:

```
> sum(3, 4, 5, 6)
[1] 18
> max(3, 4, 5, 6)
[1] 6
> min(3, 4, 5, 6)
[1] 3
```

Arguments can be named or unnamed, but if they are unnamed they
must be ordered (we will see later how to find the right order).

```
> seq(from=2, to=10, by=2)
[1] 2 4 6 8 10
> seq(2, 10, 2)
[1] 2 4 6 8 10
```

 The basic data structure in R is a vector – an ordered collection of values. R even treats single values as 1-element vectors. The function c() combines its arguments into a vector:

```
> x <- c(3, 4, 5, 6)
> x
[1] 3 4 5 6
```

 As mentioned, the square brackets [] indicate position within the vector (the index). We can extract individual elements by using the [] notation:

```
> x[1]
[1] 3
> x[4]
[1] 6
```

We can even put a vector inside the square brackets (vector indexing):

```
> y <- c(2, 3)
> x[y]
[1] 4 5
```

There are a number of shortcuts to create a vector. Instead of:

```
> x <- c(3, 4, 5, 6, 7, 8, 9, 10, 11, 12)
```

we can write:

```
> x < - 3:12
```

or we can use the seq() function, which returns a vector:

```
> x <- seq(2, 10, 2)
> x
  [1] 2 4 6 8 10
> x <- seq(2, 10, length.out = 7)
• > x
  [1] 2.00000 3.33333 4.66667 6.00000 7.33333 8.66667 10.00000
```

• or the **rep()** function:

```
> y <- rep(3, 5)
> > y
[1] 3 3 3 3 3
> y <- rep(1:3, 5)
> y
[1] 1 2 3 1 2 3 1 2 3 1 2 3 1 2 3
```

We have seen some ways of extracting elements of a vector. We can
use these shortcuts to make things easier (or more complex!)

```
> x <- 3:12
> x[3:7]
[1] 5 6 7 8 9
> x[seq(2, 6, 2)]
[1] 4 6 8
> x[rep(3, 2)]
[1] 5 5
```

We can add an element to a vector

```
> y <- c(x, 1)
> y
[1] 3 4 5 6 7 8 9 10 11 12 1
```

We can glue vectors together

```
> z <- c(x, y)
> z
[1] 3 4 5 6 7 8 9 10 11 12 3 4 5 6 7 8 9 10 11 12 1
```

We can remove element(s) from a vector

```
> x <- 3:12
> x[-3]
  [1] 3 4 6 7 8 9 10 11 12
> x[-(5:7)]
  [1] 3 4 5 6 10 11 12
> x[-seq(2, 6, 2)]
  [1] 3 5 7 9 10 11 12
```

Finally, we can modify the contents of a vector

```
> x[6] <- 4
> x
[1] 3 4 5 6 7 4 9 10 11 12
> x[3:5] <- 1
> x
[1] 3 4 1 1 1 4 9 10 11 12
```

 Remember! Square brackets for indexing [], parentheses for function arguments ().

### Basic concepts in R vector arithmetic

 When applying all standard arithmetic operations to vectors, application is element-wise

```
> x <- 1:10
> y <- x*2
> y
[1] 2 4 6 8 10 12 14 16 18 20
> z <- x^2
> z
[1] 1 4 9 16 25 36 49 64 81 100
```

Adding two vectors

```
> y + z
[1] 3 8 15 24 35 48 63 80 99 120
```

If vectors are not the same length, the shorter one will be recycled:

```
> x + 1:2
[1] 2 4 4 6 6 8 8 10 10 12
```

But be careful if the vector lengths aren't factors of each other:

```
> x + 1:3
```

#### Basic concepts in R Character vectors and naming

 All the vectors we have seen so far have contained numbers, but we can also store strings in vectors – this is called a character vector.

```
> gene.names <- c("Pax6", "Beta-actin", "FoxP2", "Hox9")</pre>
```

 We can name elements of vectors using the names function, which can be useful to keep track of the meaning of our data:

 We can also use the **names** function to get a vector of the names of an object:

### Exercise: genes and genomes

 Let's try some vector arithmetic. Here are the genome lengths and number of protein coding genes for several model organisms:

	Genome size (Mb)	Protein coding genes
Homo sapiens	3,102	20,774
Mus musculus	2,731	23,139
Drosophila melanogaster	169	13,937
Caenorhabditis elegans	100	20,532
Saccharomyces cerevisiae	12	6,692

 Create genome.size and coding.genes vectors to hold the data in each column using the c function. Create a species.name vector and use this vector to name the values in the other two vectors.

### Exercise: genes and genomes

- Let's assume a coding gene has an average length of 1.5 kilobases.
   On average, how many base pairs of each genome is made of coding genes? Create a new vector to record this called coding.bases.
- What percentage of each genome is made up of protein coding genes?
   Use your coding.bases and genome.size vectors to calculate this.
   (See earlier slides for how to do division in R.)
- How many times more bases are used for coding in the human genome compared to the yeast genome? How many times more bases are in the human genome in total compared to the yeast genome? Look up indices of your vectors to find out.

#### Answers to genome exercise

Creating vectors:

```
> genome.size<-c(3102,2731,169,100,12)
> coding.genes<-c(20774,23139,13937,20532,6692)
> species.name<-c("H. sapiens","M. musculus","D. melanogaster","C. elegans","S. cerevisiae")
> names(genome.size)<-species.name
> names(coding.genes)<-species.name</pre>
```

- To calculate the number of coding bases, we need to use the same scale as we used for genome size: 1.5 kilobases is 0.0015 Megabases.
  - > coding.bases<-coding.genes\*0.0015</pre>
  - > coding.bases

```
H. sapiens M. musculus D. melanogaster C. elegans S. cerevisiae
31.1610 34.7085 20.9055 30.7980 10.0380
```

### Answers to genome exercise

To calculate the percentage of coding bases in each genome:

```
> coding.pc<-coding.bases/genome.size*100
> coding.pc

H. sapiens M. musculus D. melanogaster C. elegans S. cerevisiae
    1.004545    1.270908    12.370118    30.798000    83.650000
```

To compare human to yeast:

```
> coding.bases[1]/coding.bases[5]
H. sapiens
    3.104304
> genome.size[1]/genome.size[5]
H. sapiens
    258.5
```

 Note that if a new vector is created using a named vector, the names are usually carried across to the new vector. Sometimes this is what we want (as for coding.pc) but sometimes it is not (when we are comparing human to yeast). We can remove names by setting them to the special NULL value:

```
> names(coding.pc)<-NULL
> coding.pc
[1] 1.004545 1.270908 12.370118 30.798000 83.650000
```

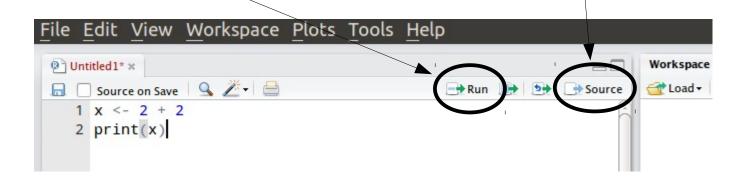

### Writing scripts with Rstudio

Typing lots of commands directly to R can be tedious. A better way is to write the commands to a file and then load it into R.

- Click on File -> New in Rstudio
- Type in some R code, e.g.

```
x <- 2 + 2
print(x)</pre>
```

Click on Run to execute the current line, and Source to execute the whole script

Sourcing can also be performed manually with source("myScript.R")

#### **Getting Help**

- To get help on any R function, type ? followed by the function name. For example:
  - > ?seq
- This retrieves the syntax and arguments for the function. You can see
  the default order of arguments here. The help page also tells you which
  package it belongs to.
- There will typically be example usage, which you can test using the example function:
  - > example(seq)
- If you can't remember the exact name type ?? followed by your guess.
   R will return a list of possibles
  - > ??plot

### Interacting with the R console

- R console symbols
  - ; end of line
    - Enables multiple commands to be placed on one line of text
  - # comment
    - indicates text is a comment and not executed
  - + command line wrap
    - R is waiting for you to complete an expression
- Ctrl-c or escape to clear input line and try again
- Ctrl-I to clear window
- Press q to leave help (using R from the terminal)
- Use the TAB key for command auto completion
- Use up and down arrows to scroll through the command history

### R packages

- R comes ready loaded with various libraries of functions called packages. e.g. the function sum() is in the base package and sd(), which calculates the standard deviation of a vector, is in the stats package
- There are 1000s of additional packages provided by third parties, and the packages can be found in numerous server locations on the web called repositories
- The two repositories you will come across the most are
  - The Comprehensive R Archive Network (CRAN)
  - Bioconductor
- CRAN is mirrored in many locations. Set your local mirror in RStudio using Tools → Options, and choose a CRAN mirror
- Set the Bioconductor package download tool by typing:
  - > source("http://bioconductor.org/biocLite.R")
- Bioconductor packages are then loaded with the biocLite() function:
  - > biocLite("PackageName")

### R packages

- 5400+ packages on CRAN:
  - Use CRAN search to find functionality you need:

http://cran.r-project.org/search.html

Or, look for packages by theme:

http://cran.r-project.org/web/views/

- 750 packages in Bioconductor:
  - Specialised in genomics:

http://www.bioconductor.org/packages/release/bioc/

- Other repositiories:
- 1700+ projects on R-forge:
  - http://r-forge.r-project.org/
- R graphical manual:
  - http://rgm3.lab.nig.ac.jp/RGM

Bottomline: **always** first look if there is already an R package that does what you want before trying to implement it yourself

# Exercise: Install Packages ggplot and DESeq

- ggplot2 is a commonly used graphics package (we will try it tomorrow).
  - Use install.packages() function...
     install.packages("ggplot2")
  - or in RStudio goto Tools → Install Packages... and type the package name
- DESeq is a BioConductor package (www.bioconductor.org)
  - Use biocLite() function
     biocLite("DESeq")
- R needs to be told to use the new functions from the installed packages
  - Use library(...) function to load the newly installed features library(ggplot2) # loads ggplot functions library(DESeq) # loads DESeq functions
  - library()
    - Lists all the packages you've got installed locally

Data structures

2

### R is designed to handle experimental data

- Although the basic unit of R is a vector, we usually handle data in data frames.
- A data frame is a set of observations of a set of variables in other words, the outcome of an experiment.
- For example, we might want to analyse information about a set of patients. To start with, let's say we have ten patients and for each one we know their name, sex, age, weight and whether they give consent for their data to be made public.

### The patients data frame

We are going to create a data frame called 'patients', which will have ten rows (observations) and seven columns (variables). The columns must all be equal lengths.

	First_Name	Second_Name	Full_Name	Sex	Age	Weight	Consent
1	Adam	Jones	<b>Adam Jones</b>	Male	<b>50</b>	70.8	TRUE
2	Eve	Parker	<b>Eve Parker</b>	<b>Female</b>	21	67.9	TRUE
3	John	Evans	<b>John Evans</b>	Male	35	75.3	FALSE
4	Mary	Davis	Mary Davis	<b>Female</b>	45	61.9	TRUE
5	Peter	Baker	Peter Baker	Male	28	72.4	<b>FALSE</b>
6	Paul	<b>Daniels</b>	Paul Daniels	Male	31	69.9	FALSE
7	Joanna	Edwards	Joanna Edwards	<b>Female</b>	42	63.5	<b>FALSE</b>
8	Matthew	Smith	Matthew Smith	Male	33	71.5	TRUE
9	David	Roberts	David Roberts	Male	<b>57</b>	73.2	FALSE
10	Sally	Wilson	Sally Wilson	<b>Female</b>	<b>62</b>	64.8	TRUE

Let's see how we can construct this from scratch.

### Character, numeric and logical data types

 Each column is a vector, like previous vectors we have seen, for example:

```
> age<-c(50, 21, 35, 45, 28, 31, 42, 33, 57, 62)
> weight<-c(70.8, 67.9, 75.3, 61.9, 72.4, 69.9, 63.5, 71.5, 73.2, 64.8)</pre>
```

We can define the names using character vectors:

```
> firstName<- c("Adam", "Eve", "John", "Mary", "Peter", "Paul", "Joanna",
"Matthew", "David", "Sally")
    > secondName<-c("Jones", "Parker", "Evans", "Davis", "Baker", "Daniels",
"Edwards", "Smith", "Roberts", "Wilson")</pre>
```

- We also have a new type of vector, the logical vector, which only contains the values TRUE and FALSE:
  - > consent<-c(TRUE, TRUE, FALSE, TRUE, FALSE, FALSE, FALSE, TRUE, FALSE, TRUE)

### Character, numeric and logical data types

 Vectors can only contain one type of data; we cannot mix numbers, characters and logical values in the same vector. If we try this, R will convert everything to characters:

We can see the type of a particular vector using the class function:

```
> class(firstName)
[1] "character"
> class(age)
[1] "numeric"
> class(weight)
[1] "numeric"
> class(consent)
[1] "logical"
```

#### **Factors**

- Character vectors are fine for some variables, like names.
- But sometimes we have categorical data and we want R to recognize this.
- A factor is R's data structure for categorical data.

- R has converted the strings of the sex character vector into two levels, which are the categories in the data.
- Note the values of this factor are not character strings, but levels.
- We can use this factor to compare data for males and females.

## Creating a data frame (first attempt)

We can construct a data frame from other objects:

> patients

```
firstName secondName paste.firstName..secondName.
                                                        sex age weight consent
                                                       Male
                                                             50
        Adam
                  Jones
                                          Adam Jones
                                                                  70.8
                                                                           TRUE
2
                 Parker
                                          Eve Parker Female
                                                             21
                                                                  67.9
                                                                          TRUE
         Eve
3
        John
                  Evans
                                          John Evans
                                                       Male
                                                                  75.3
                                                                          FALSE
                                          Mary Davis Female
                                                                  61.9
4
        Mary
                  Davis
                                                             45
                                                                          TRUE
5
      Peter
                  Baker
                                         Peter Baker
                                                       Male
                                                             28 72.4
                                                                         FALSE
6
        Paul
                Daniels
                                        Paul Daniels
                                                       Male
                                                             31
                                                                  69.9
                                                                         FALSE
                                      Joanna Edwards Female
7
                Edwards
                                                             42
                                                                  63.5
                                                                         FALSE

                                                             33
                                                                  71.5
                                                                          TRUE
9
       David
                Roberts
                                       David Roberts
                                                       Male
                                                             57
                                                                  73.2
                                                                          FALSE
10
       Sally
                 Wilson
                                        Sally Wilson Female 62
                                                                  64.8
                                                                           TRUE
```

- The paste function joins character vectors together.
- We can access particular variables using the dollar operator:

```
> patients$age
1] 50 21 35 45 28 31 42 33 57 62
```

## Naming data frame variables

- R has inferred the names of our data frame variables from the names of the vectors or the commands (eg the paste command).
- We can name the variables after we have created a data frame using the **names** function, and we can use the same function to see the names:

```
    > names(patients)<-c("First_Name", "Second_Name", "Full_Name", "Sex", "Age", "Weight", "Consent")</li>
    > names(patients)
        [1] "First_Name" "Second_Name" "Full_Name" "Sex" "Age"
    "Weight" "Consent"
```

Or we can name the variables when we define the data frame:

### Factors in data frames

 When creating a data frame, R assumes all character vectors should be categorical variables and converts them to factors. This is not always what we want:

 We can avoid this by asking R not to treat strings as factors, and then explicitly stating when we want a factor by using factor:

# Matrices matrix(..., ncol=..., nrow=...)

Data frames are R's speciality, but R also handles matrices:

```
> e <- matrix(1:10, nrow=5, ncol=2)</pre>
> e
     [,1] [,2]
[1,]
[2,]
[3,]
[4,]
[5,]
            10
> f \leftarrow matrix(1:10, nrow=2, ncol=5)
> f
     [,1] [,2] [,3] [,4] [,5]
[1,]
[2,]
                            10
> f %*% e
     [,1] [,2]
      95 220
[1,]
[2,]
      110 260
```

The \*\*\* operator is the matrix multiplication operator, not the standard multiplication operator.

### Lists

### list(name1=obj1, name2=obj2, ...)

- We have seen that vectors can only hold data of one type. How can we store data of multiple types? Or vectors of different lengths in one object?
- We can use lists. A list can contain objects of any type.

```
one.to.ten <- 1:10
uniform.mat <- matrix(runif(100),ncol=10,nrow=10)
year.to.october <- data.frame(one.to.ten, month.name[1:10])
myList<-list( ls.obj.1=one.to.ten, ls.obj.2=uniform.mat, ls.obj.3=year.to.october )
names(myList)</pre>
```

 We can use the dollar syntax to access list items (in fact, a data frame is a special type of list):

```
myList$ls.obj.1
```

- We can also use myList[[1]] to get the first item in the list.
- (For the curious: this double indexing is necessary because lists are in fact just like vectors they
  can only contain one type of object. But one of the types they can contain is a list. So any list like
  the above is actually a list of lists; the first element myList[1] is a list containing a vector, and so
  we need double indexing to actually get the vector.)

# Indexing data frames and matrices

```
Special cases:
a[i, ] i-th row
a[,j] j-th column
```

 You can index multidimensional data structures like matrices and data frames using commas. If you don't provide an index for either rows or columns, all of the rows or columns will be returned.

```
object [ rows , columns ]
> e[1,2]
[1] 6
> e[1,]
[1] 1 6
> patients[1,2]
[1] "Jones"
> patients[1,]
  First_Name Second_Name Full_Name Sex Age Weight Consent
1 Adam Jones Adam Jones Male 50 70.8 TRUE
```

## Advanced indexing

 As values in R are really vectors, so indices are actually vectors, and can be numeric or logical:

```
> s <- letters[1:5]
> s[c(1,3)]
[1] "a" "c"
> s[c(TRUE, FALSE, TRUE, FALSE, FALSE)]
[1] "a" "c"
> a < -1:5
> a<3
[1] TRUE TRUE FALSE FALSE FALSE
> s[a<3]
[1] "a" "b"
> s[a>1 & a<3]
[1] "b"
> s[a==2]
[1] "b"
```

## Operators

arithmetic

(equal to, not equal to)

comparison

logical

these always return logical values! (TRUE, FALSE)

### Exercise

- Create a data frame called my.patients using the instructions in the slides. Change the data if you like.
- Check you have created the data frame correctly by loading the original version from this file in the Day\_1\_scripts folder using source:
  - > source("1.2\_patients.R")
- Remake your data frame with three new variables: country, continent, and height. Make up the data. Make country a character vector but continent a factor.
- Try the **summary** function on your data frame. What does it do?
   How does it treat vectors (numeric, character, logical) and factors?
   (What does it do for matrices?)
- Use logical indexing to select the following patients:
  - Patients under 40
  - Patients who give consent to share their data
  - Men who weigh as much or more than the average European male (70.8 kg)

## Logical indexing answers

- Patients under 40:
  - > patients[patients\$Age<40,]</pre>
- Patients who give consent to share their data:
  - > patients[patients\$Consent==TRUE,]
- Men who weigh as much or more than the average European male (70.8 kg):
  - > patients[patients\$Sex=="Male" & patients\$Weight>=70.8,]

R for data analysis

3

# 3 steps to Basic data analysis

### 1. Reading in data

- read.table()
- read.csv(), read.delim()

### 2. Analysis

- Manipulating & reshaping the data
- Any maths you like
- Plotting the outcome
  - High level plotting functions (covered tomorrow)

### 3. Writing out results

- write.table()
- write.csv()

## A simple walkthrough Exemplifies 3 steps to R analysis

- 50 neuroblastoma patients were tested for NMYC gene copy number by interphase nuclei FISH
  - Amplification of NMYC correlates with worse prognosis
  - We have count data
    - Numbers of cells per patient assayed
      - For each we have NMYC copy number relative to base ploidy
- We need to determine which patients have amplifications
  - (i.e >33% of cells show NMYC amplification)

# Step 1. Read in the data

Patient	Nuclei	NB_Amp	NB_Nor	NB_Del
1	44	0	41	3
2	67	3	58	6
3	33	7	26	0
4	36	6	30	0
5	51	5	45	1
6	43	0	38	5
7	64	1	56	7
8	58	2	49	7
9	56	0	53	3
10	66	0	56	10
11	33	13	19	1

We need to read in the results table and assign it to an object (rawData)

If the data had been comma separated values, then sep="," read.csv("1.3\_NBcountData.csv")
?read.table for a full list of arguments

1.3\_NBcountData.R (script commands)

1.3\_NBcountData.txt (data file)

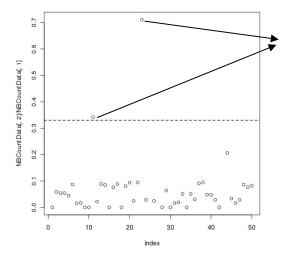

## Handling missing values

- The data frame contains some 'NA' values, which means the values are missing – a common occurrence in real data collection.
- NA is a special value that can be present in objects of any type (logical, character, numeric etc).
- NA is not the same as NULL. NULL is an empty R object. NA is one missing value within an R object (like a data frame or a vector).
- Often R functions will handle NAs gracefully, but sometimes we have to tell the functions what to do with them. R has some built-in functions for dealing with NAs, and functions often have their own arguments (like na.rm) for handling them.

```
> x<-c(1,NA,3)
> mean(x)
[1] NA
> mean(x,na.rm=TRUE)
[1] 2
> mean(na.omit(x))
[1] 2
> is.na(x)
[1] FALSE TRUE FALSE
```

# Step 2. Analysis (reshaping data & maths)

- Our analysis involves identifying patients with > 33% NB amplification
  - prop <- rawData\$NB\_Amp / rawData\$Nuclei # create an index of results
  - amp <- which(prop > 0.33) # Get sample names of amplified patients
- We can plot a simple chart of the % NB amplification
  - plot(prop, ylim=c(0,1))
  - abline(h=0.33)

These 2 samples are amplified (11 & 23)

# Step 3. Outputting the results

- We write out a data frame of results (patients > 33% NB amplification) as a 'comma separated values' text file
  - write.csv(rawData[amp,],file="selectedSamples.csv") #
     Export table, file name = selectedSamples.csv
    - Files are directly readable by Excel and Calc
- Its often helpful to double check where the data has been saved
  - Use get working directory function
    - getwd() # print working directory

## Data analysis exercise: Which samples are near normal?

Patients are near normal if:

```
(NB\_Amp/Nuclei < 0.33 \& NB\_Del == 0)
```

Modify the condition in our previous code to find these patients

 Write out a results file of the samples that match these criteria, and open it in a spreadsheet program

# Solution to NB normality test Basic data analysis

```
> norm <- which( prop < 0.33 & rawData$NB_Del==0)
> norm

[1] 3     4     7     15     20     24     36     37     42     47

> write.csv(rawData[norm,],"My_NB_output.csv")
```

R programming techniques

# Basic R 'Built-in' functions for working with objects

 R has many built-in functions for doing simple calculations on objects. Start with a random sample of 15 numbers from 1 to 100 and try the functions below.

```
> x<-sample(100,15)
```

- Arithmetic with vectors
  - Min / Max value number in a series

```
min(x); max(x)
```

Sum of values in a series

#### sum(x)

Average estimates (mean / median)

```
mean(x); median(x)
```

Range of values in a series

#### range(x)

Variance

```
var(x)
```

- Arithmetic with vectors
  - Rank ordering

#### rank(x)

Quantiles

#### quantile(x); boxplot(x)

Square Root

#### sqrt(x)

Standard deviation

#### sd(x)

Trigonometry functions

```
tan(x); cos(x); sin(x)
```

# Basic R 'Built-in' functions for working with data frames

We have seen before how we can get the names of our variables, but for dataframes and matrices we can
also get these names with colnames, and the names of the rows with rownames:

```
> names(patients)
[1] "First_Name" "Second_Name" "Full_Name"
                                                 "Sex"
                                                            "Age"
                                                                       "Weight"
                                                                                      "Consent"
> colnames(patients)
[1] "First Name" "Second Name" "Full Name"
                                                 "Sex"
                                                                       "Weight"
                                                                                      "Consent"
                                                            "Age"
> rownames(patients)
               "3" "4" "5" "6"
                                          "8"
We can get the numbers of rows or columns with nrow and ncol:
> nrow(patients)
[1] 10
> ncol(patients)
[1] 7
We can also find the length of a vector or a list with length, although this may give confusing results for some
   structures, like data frames:
> length(c(1,2,3,4,5))
[1] 5
> length(patients)
[1] 7
> length(patients$Age)
[1] 10
```

Remember, a data frame is a list of variables, so its length is the number of variables. The length of one of the variable vectors (like Age) is the number of observations.

# Basic R 'Built-in' functions for working with data frames

We can add rows or columns to a data frame using **rbind** and **cbind**:

```
> newpatient<-c("Kate", "Lawson", "Kate Lawson", "Female", "35", "62.5", "TRUE")</pre>
```

> rbind(patients, newpatient)

```
First Name Second Name
                              Full Name
                                           Sex Age Weight Consent
        Adam
                                          Male 50
1
                             Adam Jones
                   Jones
                                                     70.8
                                                             TRUE
                  Parker
                             Eve Parker Female
2
         Eve
                                                21
                                                     67.9
                                                             TRUE
                   Evans
                                          Male
        John
                             John Evans

                  Wilson
                                                     64.8
                                                             TRUE
10
                                                62
                            Kate Lawson Female
11
        Kate
                                                35
                                                     62.5
                  Lawson
                                                             TRUE
```

We can also remove rows and columns:

```
patients[-1,] # remove first row
patients[,-1] # remove first column
```

<sup>&</sup>gt; cbind(patients, 10:1)

# Basic R 'Built-in' functions for working with data frames

Sorting a vector with **sort**:

```
> sort(patients$Second_Name)
```

```
[1] "Baker" "Daniels" "Davis" "Edwards" "Evans" "Jones" "Parker" "Roberts" "Smith" "Wilson"
```

Sorting a data frame by one variable with **order**:

> order(patients\$Second\_Name)

```
[1] 5 6 4 7 3 1 2 9 8 10
```

> patients[order(patients\$Second\_Name),]

	First_Name	Second_Name	Full_Name	Sex	Age	Weight	Consent
5	Peter	Baker	Peter Baker	Male	28	72.4	FALSE
6	Paul	<b>Daniels</b>	Paul Daniels	Male	31	69.9	FALSE
4	Mary	Davis	Mary Davis	<b>Female</b>	45	61.9	TRUE
7	Joanna	<b>Edwards</b>	Joanna Edwards	<b>Female</b>	42	63.5	FALSE
3	John	Evans	<b>John Evans</b>	Male	35	75.3	FALSE
1	Adam	Jones	Adam Jones	Male	<b>50</b>	70.8	TRUE
2	Eve	Parker	<b>Eve Parker</b>	<b>Female</b>	21	67.9	TRUE
9	David	Roberts	David Roberts	Male	<b>57</b>	73.2	FALSE
8	Matthew	Smith	Matthew Smith	Male	33	71.5	TRUE
10	Sally	Wilson	Sally Wilson	<b>Female</b>	<b>62</b>	64.8	TRUE

## The R workspace

- The objects we have been making are created in the R workspace.
- When we load a package, we are loading that package's functions and data sets into our workspace.
- You can see what is in your workspace with Is:
- > 1s()
- You can attach data frames to your workspace and then refer to the variables directly:
- > attach(patients)
- > Full\_Name
- You can remove objects from the workspace with **rm**:

```
> x<-1:5
[1] 1 2 3 4 5
> rm(x)
> x
Error: object 'x' not found
```

• You can remove everything by giving **rm** a list of all the objects returned by **ls**:

```
> rm(list=ls())
```

## The R workspace

- Your workspace is like an unsaved Word document.
- When you quit R, it will usually save your workspace to a hidden file called '.Rdata' in your current directory. This workspace will be loaded again if you open R in the same directory.
- This file is a binary, computer-readable file, not a human-readable file, which you have to open with R (like a Word document in Office).
- It is safer to explicitly save your workspace using **save.image**:
- > save.image("phd.chapter.1.R")
- This way, if you are working on several different projects, you can make sure the objects for each project are saved to named files, rather than trying to remember which directory you were working in, or risking overwriting some objects you forgot about and need later.
- To load a particular image, use **load**:
- > load("phd.chapter.1.R")

## Packages in the R workspace

• You can see which packages are loaded into your workspace with **search**:

```
> search()
```

```
[1] ".GlobalEnv" "tools:rstudio" "package:stats" "package:graphics"
[5] "package:grDevices" "package:utils" "package:datasets" "package:methods"
[9] "Autoloads" "package:base"
```

- .GlobalEnv is where all the objects you create are stored.
- Most of the core functions are in **stats**, **utils**, **methods** and **base**.
- We will cover graphics and grDevices tomorrow afternoon.
- **Search** shows the search path R runs through whenever you use an object or function name. It will first look in your global environment, then in the **Rstudio** tools (if using Rstudio), then in the **stats** package and so on.
- When loading packages, you will often see warnings about some objects or functions being 'masked'. This means that the newly loaded package contains an object with the same name as some object in a package that is already loaded. R will use the object in the new package whenever it comes across the name, because the new package will be earlier in the search path.

## Introducing loops

- Many programming languages have ways of doing the same thing many times, perhaps changing some variable each time.
   This is called looping.
- Loops are not used in R so often, because we can usually achieve the same thing using vector calculations.
- For example, to add two vectors together, we do not need to add each pair of elements one by one, we can just add the vectors.
- But there are some situations where R functions can not take vectors as input. For example, read.csv will only load one file at a time.
- What if we had ten files to load in, all ending in the same extension (like .csv)?

## Introducing loops

We could do this: > colony<-data.frame() # Start with empty data frame</pre> > colony1<-read.csv("1.4\_colony\_Run1Counts.csv")</pre> > colony2<-read.csv("1.4\_colony\_Run2Counts.csv")</pre> > colony3<-read.csv("1.4\_colony\_Run3Counts.csv")</pre> > colony10<-read.csv("1.4\_colony\_Run10Counts.csv")</pre> > colony<-rbind(colony1, colony2, colony3, ..., colony10)</pre> But this will be boring to type, difficult to change, and prone to error.

 As we are doing the same thing 10 times, but with a different file name each time, we can use a loop instead.

### **LOOPS**

### Commands & flow control

R has two basic types of loop:

for loop: run some code on every value in a vectorwhile loop: run some code while some condition is true

Here are two simple examples of these loops:

```
for (f in 1:10) {
    print(f)
}

i <- 1
while ( i <= 10 ) {
    print(i)
    i <- i + 1
}</pre>
when this condition is
false the loop stops
```

### LOOPS

### Commands & flow control

- Here's how we might use a for loop to load in our CSV files.
- If the data files are in your current working directory, we can look up files containing a particular substring in their name using the dir function:

```
dir(pattern="Counts.csv")
[1] "1.4_colony_Run1Counts.csv" "1.4_colony_Run2Counts.csv"
    "1.4_colony_Run3Counts.csv"

• So we can load all the files using a for loop as follows:
colony<-data.frame()
countfiles<-dir(pattern="Counts.csv")
for (file in countfiles) {
    t<-read.csv(file)
    colony<-rbind(colony,t)
}</pre>
```

Here, we use a temporary variable t to store the data in each file, and then
add that data to the main colony data frame.

## Conditional branching Commands & flow control

- Use an if statement for any kind of condition testing.
- Different outcomes can be selected based on a condition within brackets.

```
if (condition) {
... do this ...
} else {
... do something else ...
}
```

- condition is any logical value, and can contain multiple conditions
  - e.g. (a==2 & b <5), this is a compound conditional argument

## Conditional branching Commands & flow control

For example, if we were writing a script to load an unknown set of files, using the **for** loop we wrote before, we might want to warn the user if we can't find any files with the pattern we are searching for. Here's how we can use an **if** statement to test for this:

```
colony<-data.frame()
countfiles<-dir(pattern="Counts.csv")

if (length(countfiles) == 0) {
    stop("No Counts.csv files found!")
} else {
    for (file in countfiles) {
        t<-read.csv(file)
        colony<-rbind(colony,t)
    }
}</pre>
```

The **stop** function outputs the error message and quits.

## Code formatting avoids bugs!

Code formatting is crucial for readability of loops

- The code between brackets {} always is indented, this clearly separates what is executed once, and what is run multiple times
- Trailing bracket } always alone on the line at the same indentation level as the initial bracket {

GOOD!

 Use white spaces to divide the horizontal space between units of your code, e.g. around assignments, comparisons

### Exercise

- 1. Output the patients data frame, with the patients sorted in order of age, oldest first. (You may need the **rev** function.)
- 2. Load in the **colony** data frame using a for loop. Three of the data files are in the  $Day\_1\_scripts$  folder. Load all three files into **colony** using the for loop in the slides.
- 3. How many observations do you have in the **colony** data frame? Find out by counting the number of rows in **colony** using the **nrow** function.
- 4. Suppose a power analysis of your data shows that you only need 48 observations to robustly test your hypothesis. This means we can stop loading files when we have loaded at least 48 observations. Modify your **for** loop so it will only load files if the **colony** data frame has less than 48 observations in it.

### Answers to exercise

1. To order the patients by decreasing age:

```
patients[rev(order(patients$Age)),]
```

3. To find the number of rows in the **colony** data frame:

```
nrow(colony)
```

4. To stop loading files after at least 48 observations have been found, use the code from the first **for** loop slide with a new **if** statement:

```
colony<-data.frame()
countfiles<-dir(pattern="Counts.csv")
for (file in countfiles) {
    if ( nrow(colony) < 48 ) {
        t<-read.csv(file)
        colony<-rbind(colony,t)
    }
}</pre>
```

## End of Day 1
